2002 DEC 30 PM 3: 3

## 2002 DEC 30 PM 3: 36

December 30, 2002

Honorable Christine Todd Whitman, Administrator United States Environmental Protection Agency PO Box 1473 Merrifield, VA 22116

Attn: EPA HPVC Challenge Program

Dear Administrator Whitman:

Enclosed please find the Data Availability and Screening Level Assessment for TCC, submitted on behalf of the TCC Consortium to the U.S. EPA's High Production Volume Chemical Challenge Program.

While the information presented in this report clearly demonstrates the completeness of knowledge with respect to the toxicity and safety of TCC, it should be noted that similar assessments (with similar conclusions regarding safety) have also been conducted by the U.S. Food and Drug Administration (FDA). These existence and conclusions of these previously conducted FDA assessments underscore our earlier recommendation to EPA that close coordination of the review of HPV chemicals with all appropriate federal agencies is essential.

The Consortium appreciates EPA's efforts in ensuring a sustainable high production volume chemical assessment program. Thank you for your attention. Please contact me if I you have any questions.

Sincerely,

Alvaro J. DeCarvalho Director of Environmental Safety

#### [1] Executive Summary

#### [1.1] Sponsor Companies

The Triclocarban (TCC) Consortium, managed by the Soap and Detergent Association (SDA), includes the following member companies: Bayer Corporation and Clariant Corporation BU-IV Biocides.

[1.2] CAS Number: 101-20-2

[1.3] Substance Name: Triclocarban

TCC

Urea, N-(4-chlorophenyl)-N'-(3,4-dichlorophenyl)

3,4,4'-Trichlorocarbanilide

#### [1.4] Structure and Synthesis

 $(C_{13}H_9Cl_3N_2O)$ :

Figure 1. Structure of Triclocarban

There are two commercial routes used for the production of TCC:

1) 4-chlorophenyl isocyanate [CAS# 104-12-1] is reacted with 3,4-dichloroaniline [CAS# 95-76-1] to give TCC.

2) 3,4-dichlorophenyl isocyanate [CAS# 102-36-3] is reacted with 4-chloroaniline [CAS# 106-47-8] to give TCC.

The purity specification in the draft USP monograph for TCC is: not less than 97.0% w/w. The purity of commercial production is > 98% w/w.

#### [1.5] Production Volume

Total tonnage of CAS# 101-20-2 [Urea, N-(4-chlorophenyl)-N'-(3,4-dichlorophenyl] reported in the 1998 IUR, from EPA's info on non-confidential report, was greater than 500,000 to 1,000,000 pounds/year (250 - 500 metric tonnes/year).

#### [1.6] Use Pattern and Function

TCC is an anti-microbial active ingredient used globally in a wide range of personal cleansing products that include deodorant soaps, detergents, cleansing lotions, and wipes. In North America, TCC is used exclusively as an antimicrobial and preservative in bar and liquid soaps and body washes.

#### [1.7] Environmental Screening Level Assessment

TCC is slightly soluble in water and non-volatile. It has been demonstrated to be inherently biodegradable and extensively removed (98%) during wastewater treatment through a combination of sorption and biodegradation processes. The potential for TCC to bioaccumulate in fish is low, having a bioconcentration factor (BCF) of 137 (whole fish wet weight) and 13 (muscle), indicating that TCC is readily metabolized and excreted.

The environmental fate of TCC during the main phase of its life-cycle (processing, and consumer use) was modeled using Exposure and Fate Assessment Screening Tool (E-FAST), a U.S. EPA screening level exposure assessment model. In addition, extensive environmental monitoring of TCC in wastewater, sewage treatment facilities and in surface water has been conducted over the last 20 years. Predicted Environmental Concentrations (PEC) from the environmental modeling work and field measurements range from 0.0013 to  $0.050~\mu g/L$ , depending on the assessment scenario.

TCC has been the subject of extensive acute and chronic ecotoxcity studies that have included algae, aquatic invertebrates, and fish. Aquatic invertebrates were found to be the sensitive taxa to TCC exposure from this data-set. The ecotoxicity endpoint employed in the TCC aquatic risk characterization was a 7-day *Ceriodaphnia* study that resulted in a chronic No Observed Effect Concentration (NOEC - defined as the highest concentration that causes an effect that is not statistically significantly different from the controls) of 1.46  $\mu$ g/L. Given the extensive acute and chronic ectotoxicity database for TCC, the U.S. EPA recommends an assessment factor of 10 be applied to the chronic toxicity value in order to account for various uncertainties in the measured data. This results in a Predicted No Effect Concentration (PNEC) of 0.146  $\mu$ g/L.

The risk to the aquatic environment is characterized by comparing the PEC to the PNEC. If the concentration in the surface water is less than the no effect concentration, then the potential for adverse effects is low. Integrating all the information currently available, the modeled and measured TCC surface water PEC does not exceed the PNEC. The risk characterization ratios (PEC/PNEC) range from 0.009 to 0.34 depending on the scenario used. The higher PEC/PNEC values are from scenarios where low surface water dilution of treated wastewater occurs. These

ratios, which are all less than 1, confirm that the potential for adverse environmental effects from the use TCC is very low.

#### [1.8] Human Health Screening Level Assessment

An extensive database of toxicology studies exists on TCC. These studies include both Screening Information Data Set (SIDS) and beyond-SIDS endpoints, and collectively demonstrate that this material possesses a low order of toxicity. Acute toxicity studies show that TCC is not measurably toxic by the oral or dermal routes. Studies indicate this material can be slightly irritating to eyes and non-irritating to the skin. TCC did not produce sensitization when investigated in 50 human volunteers using the Shelanski Patch Test method. TCC was also neither a primary irritant or a fatiguing agent.

The potential for systemic toxicity and functional alterations resulting from repeated exposure to TCC was evaluated in subchronic and chronic toxicity studies by the oral exposure route in rats. No adverse effects were seen in rats dosed at 1000 mg/kg bw/day for 30 days. A chronic (24 month) oral study in rats demonstrated testicular degeneration, anemia, and microscopic changes in various organs at 75 mg/kg bw/day. A No Observed Effect Level (NOEL) was established at 25 mg/kg bw/day. A three generation oral study in rats demonstrated no effect on mating indices and male fertility at all doses tested. The pregnancy rates for all groups (except second litter of the F1 generation at the highest dose) were comparable to the control group. No treatment-related effects were seen on any pups from all generations.

An assessment of the *in vitro* genotoxicity potential of TCC shows no evidence of mutagenic or clastogenic activity. A carcinogenicity study in rats demonstrated no evidence of a dose-related increase in tumor incidence at any site.

In summary, the toxicological profile of TCC indicates that the material has a low order of toxicity, based on a variety of acute, sub-chronic, and chronic studies.

#### [1.8.1] Exposure Data

TCC is used in personal cleansing products as an antimicrobial ingredient. Based on this use, workers and consumers may be exposed to TCC although the type of exposure for these two populations is different.

#### **Worker Exposure**

For workers, inhalation and dermal exposure to TCC during the production, formulation, or transportation process is limited due to the low volatility of TCC and the industrial hygiene standards and personal protective equipment that are utilized as a standard practice in production facilities. Employee exposure is minimized through engineering controls and good industrial hygiene practices. Processing experience with a variety of ingredients in the manufacturing of personal cleansing products confirms that these practices are effective in minimizing worker exposure.

#### Consumer Exposure (Direct Exposure)

The potential for consumer exposure to TCC is very limited. Based on the chemistry and low level of deposition there is negligible consumer exposure to this material under recommended use situations (see Table 1.2). This assessment is based on a thorough attempt to identify the intended and reasonably foreseeable uses for personal care products containing this material and to assess those resultant exposures. The most relevant and anticipated exposure for TCC to consumers is by dermal exposure. Dermal exposure can result from hand, face or body washing with either bar soap, liquid soap, or body wash containing TCC. Due to the rinse-off nature of this product type, a low level of deposition of the material is anticipated. For example, the consumer is estimated to be exposed to only 1.4% of the applied TCC when a bar soap containing 1.5% TCC is used under normal circumstances (North-Root et al., 1984). Based on the results of a Soap and Detergent Association Use and Exposure Survey (SDA, 2002), bar soaps contain levels of TCC which range from 0.5 to 5% in the final formulation, liquid soaps contain TCC at levels ranging from 1 to 5% and body washes may contain from 0.1 - 0.5% in the final formulation. It is worth noting that the range of TCC in product identified here for the exposure assessment is broad due to the reporting ranges used in the SDA survey. Actual concentrations in bar soaps are expected to be limited to a maximum of 1.5%. Regardless, the upper end of each range for TCC was used to estimate the "worst case" exposure where washing the face, hands and body was assumed for each of these product types. Hence, a bar soap containing 5% TCC is estimated to result in exposure of 0.001 mg TCC/kg bw/day. Exposure from liquid soaps used for washing the hands and body also result in an estimate of 0.001 mg TCC/kg bw/day. Body washes formulated with TCC contain the lowest level of this ingredient and under the "worst case" scenario may result in an exposure of 0.0001 mg TCC/kg bw/day. For these dermal exposures, an absorption value of 0.39% was used based on published work conducted by Scharpf et al. in 1975. No inhalation exposure to the consumer is expected due to the low vapor pressure of TCC. Additionally, there is no anticipated oral exposure under recommended use conditions.

#### Consumer Exposure (Indirect Exposure)

No inhalation exposure is anticipated due to the low vapor pressure of TCC. Exposure calculations based on estimates of TCC in drinking water using the EPA's E-FAST model resulted in estimated values of 1.38 x 10<sup>-6</sup> mg/kg bw/day. E-FAST provides screening level estimates of concentrations of chemicals released to the environment from consumer products and is designed to provide high end to bounding estimates of exposure as is appropriate for screening level risk characterizations. Indirect exposure to TCC from ingestion of fish was also determined to be negligible because the potential for TCC to bioconcentrate is minimal based on a BCF of 138 (whole fish wet weight) and 13 (muscle).

#### Children's Exposure (Direct Exposure)

Exposure of children to TCC is anticipated based on the recommended use of the personal cleansing products that utilize TCC. As with adults, the dermal route is the main pathway by which children would be exposed to TCC. For all exposure assessments, a child's body weight of 10 kg was assumed based on data released by the Center for Disease Control in 2002

(National Health and Nutrition Examination Survey Results (NHANES), 2002). A 10 kg child represents a 95<sup>th</sup> percentile 7 month old boy. Additionally, for these dermal exposures, an assumption of 0.39% absorption is made based on published work (Scharpf et al., 1975). Hence, a bar soap containing 5% TCC is estimated to result in exposure of 0.005 mg TCC/kg bw/day. Exposure from liquid soaps used for washing the hand and body result in an estimate of 0.006 mg TCC/kg bw/day. Body washes formulated with TCC contain the lowest level of this ingredient and under the "worst case" scenario may result in an exposure of 0.0004 mg TCC/kg bw/d.

#### Children's Exposure (Indirect Exposure)

No inhalation exposure is anticipated due to the low vapor pressure of TCC. There may be accidental ingestion of bars, liquid soaps or body washes containing TCC by children; however, these would be infrequent and would result in mild transient symptoms, if any are present, such as nausea, vomiting and/or diarrhea. Such effects would be consistent with the effects observed following accidental ingestion of other surfactant based products and could be attributed to the surfactant and not TCC.

#### **Summary of Human Health Assessment:**

The data summarized above demonstrate that TCC has an acceptable safety profile for use in personal cleansing products. The risk to human health is characterized by comparing the estimated human exposure to the NOEL from animal studies. The amount by which the NOEL exceeds the estimated exposure is referred to as the margin of exposure (MOE). The MOE should be sufficiently large to account for several sources of uncertainty and variability in extrapolating data from animal studies to humans. Based on the data presented, no adverse effects for humans are expected via any relevant exposure route. The "worst-case" dermal exposure to TCC would result from use of a liquid soap containing TCC for all hand and body washings daily by a 10 kg child. This scenario results in an estimated exposure of 0.006 mg TCC/kg bw/day (see "Children's Exposure" section above for more details). For potential oral exposure, if one assumes that TCC would be present in drinking water and not removed in wastewater treatment facilities, the calculated exposure using E-FAST would be 1.38 x 10<sup>-6</sup> mg/kg bw/day. The NOEL in the oral chronic study was 25 mg/kg bw/day. Comparing the estimated oral exposure to the oral NOEL results in an MOE of many orders of magnitude difference, even after accommodating inter- and intra-species variation. In evaluating this conservative estimate, the MOE is acceptable.

#### [1.9] HPV Endpoint Data Assessment

Each of the reports obtained was reviewed to determine adequacy according to EPA criteria and reliability per Klimisch *et al.* (1997). Robust summaries were prepared for SIDS endpoints, as well as several relevant beyond SIDS endpoints, with available and reliable data for TCC. These summaries are provided in Appendix A and are identified in Table 1.1.

Table 1.1. HPV Endpoint Data Assessment

ENDPOINT	Data Available	Data Reliable *		
Physical Chemical Characteristics				
Melting Point	Yes	Yes		
Boiling Point	Yes	Yes		
Vapor Presure	Yes	Yes		
Partition Coefficient	Yes	Yes		
Water Solubility	Yes	Yes		
Environmental Fate	-			
Photodegradation	Yes	Yes		
Stability in Water	Yes	Yes		
Transport (Fugacity)	Yes	Yes		
Biodegradation	Yes	Yes		
Ecotoxicity		l		
Acute Toxicity to Fish	Yes	Yes		
Acute Toxicity to Aquatic Invertebrates	Yes	Yes		
Acute Toxicity to Aquatic Plants	Yes	Yes		
Mammalian Toxicity		- 1		
Acute Toxicity	Yes	Yes		
Genetic Toxicity: Ames	Yes	Yes		
Genetic Toxicity: Chromosome Aberration	Yes	Yes		
Repeated Dose Toxicity	Yes	Yes		
Reproductive Toxicity	Yes	Yes		
Developmental Toxicity/Teratogenicity	Yes	Yes		
Non-SIDS Endpoints	-	'		
Eye Irritation	Yes	Yes		
Skin Irritation	Yes	Yes		
Skin Sensitization	Yes	Yes		
Carcinogenicity	Yes	Yes		

<sup>\*</sup> In accordance with the HPV Guidelines (U.S. EPA, 1999) (i.e. Determining Adequacy of Existing Data) (U.S. EPA, 1999), data reliability was established following the criteria described by Klimisch and others (1997).

#### [1.10] Sponsor's Conclusions and Recommendation

The available data on TCC hazard and exposure demonstrates that there is negligible likelihood of harm to man and the environment during manufacture of TCC and formulation and use of personal cleansing products containing TCC (See Tables 1.2 and 1.3). Data for all SIDS and other relevant endpoints are available, reliable and demonstrate that the material possesses a low order of toxicity. Aquatic PEC/PNEC ratios for TCC ranged from 0.009 to 0.34 and confirm that the potential for adverse effects to the environment are very low. Exposure to TCC in the workplace is limited due to low vapor pressure of TCC and through engineering controls and good industrial hygiene practices. Consumer evaluations indicate that MOE are acceptable and calculations supporting these estimates are conservative. Considering the completeness, accuracy, and relevance of both the hazard and exposure evaluations, TCC is concluded to be sufficiently studied and recommended as a low priority for further work.

Table 1.2. Consumer Risk Characterization

ROUTE	EXPOSURE	RESULTING DOSE*	NOEL	MOE
Dermal				
bar soap	0.1 mg /kg bw/day	0.005 mg/kg bw/day	25 mg/kg bw/day	5000
liquid soap	0.11 mg/kg bw/day	0.006 mg/kg bw/day	25 mg/kg bw/day	4167
bodywash	0.07 mg/kg bw/day	0.0004 mg/kg bw/day	25 mg/kg bw/day	62,500
Oral				
Drinking water	Not applicable	1.38 x 10 <sup>-6</sup> mg/kg bw/day**	25 mg/kg bw/day	18,115,942

<sup>\*</sup> The resulting dose takes into account the estimated dermal absorption of TCC of 0.39% based on a published report (Scharpf et al, 1975).

Table 1.3. Environmental Risk Characterization

	PEC (? g/L)	PNEC (? g/L)	PEC/PNEC (10 <sup>th</sup> /50 <sup>th</sup> percentile)
Measured	0.050 (high end)	0.146	0.34
Calculated	0.0013 (median) 0.017 (high end)	0.146 0.146	0.009 0.116

<sup>\*\*</sup> The resulting dose was calculated using EPA's E-FAST model.

#### [2] Environmental Assessment

#### [2.1] Introduction

The environmental hazard assessment is based on a combination of modeling, laboratory studies and actual field monitoring to establish the key environmental fate pathways and characterize TCC ecotoxicity. Each of the study reports used for this assessment was reviewed to determine adequacy according to U.S. EPA criteria and reliability as per Klimisch et al. (1997). Robust summaries were prepared for each report with the scores assigned according to the guidelines recommended by the U.S. EPA (U.S. EPA, 1999) for each study type. These methods include consideration of the reliability, relevance and adequacy of the data in evaluating their usefulness for hazard assessment purposes. Robust summaries for endpoints with available and reliable data for TCC are provided in Appendix A (IUCLID data set). Data essential for the environmental risk characterization of TCC is summarized in Tables 2.1 to 2.3.

Table 2.1. Physical/Chemical Property Data

PARAMETER	RESULT	Unit	REFERENCE
Molecular Weight	315.6	g/mol	Hawley's Chemical Dictionary, 11th ed.
Melting Point	250	°C	Hawley's Chemical Dictionary, 11th ed.

ECOTOXICITY	SPECIES	RESULT	PROTOCOL
Toxicity to Aquatic Plants (Algae)	Navicula pelliculosa	Minimum Algistatic Concentration (MAC, 5 day) = 6 ?g/L	Method based on Payne and Hall (1979), Monsanto study #BP-90- 9-151R
Chronic Toxicity to aquatic Invertebrates	Ceriodaphnia dubia	NOEC (21 day) = 1.46 ?g/L	OECD Guideline 202
Chronic toxicity to fish	Pimephales promelas	NOEC (35 day) = 5 ?g/L	Critcal Life Stage Test (Monsanto, 1992)

\*Only the key studies essential for the environmental risk characterization of TCC are presented in the table. Please see Appendix A for Robust Summaries of these studies and Appendix B for the complete list of all available ecotoxicity studies.

#### [2.2] Fugacity Modeling

Fugacity modeling was performed to estimate the transport and distribution of TCC into environmental compartments. Given that TCC is predominantly used in personal care products with a down-the-drain disposal route, water is the main entry compartment for this chemical. To model the partitioning of TCC upon its entry to the aquatic compartment, Level III EQC model (Mackay et al., 1996) was used with the chemical input parameters shown in Table 2.1. TCC is not readily biodegradable, however, it is biodegradable inherently, with the mineralization rate of 50% after 10 hour incubation in adapted domestic activated sludge (Gledhill, 1975, Table 2.2). For this type of substance, the Interim U.S. EPA Guidance recommends using an aquatic half-life (t<sub>1/2</sub>) of 100 days in multimedia models. Likewise, following the recommendations of the Guidance, the half-lives for the sediment and soil compartments were 100 days and 400 days, respectively. The EQC model predicted that 70% of TCC released to the aquatic compartment would stay there, with the rest partitioning to sediment (Table 2.2). The fraction partitioning to the atmosphere is negligible. Thus, the aquatic compartment is the key environmental compartment for TCC. The environmental risk characterization of TCC presented in this document therefore focuses on the aquatic compartment.

#### [2.3] Environmental Fate

#### [2.3.1] Summary of Biodegradation Data

Even though TCC is not readily biodegradable, it was shown to biodegrade in adapted activated sludge, with 100% loss of the parent compound and 50% mineralization rate (Gledhill, 1975). This is supported by the data from the Continuous Activated Sludge (CAS) study, where the removal of TCC was 98% with mineralization (measured as CO<sub>2</sub>) accounting for 56% of the total loss (Gledhill, 1975).

#### [2.3.2] Removal of TCC in Wastewater Treatment Plants

#### **Calculated:**

Sorption to activated sludge and biodegradation are expected to be the key removal processes of TCC during wastewater treatment. For compounds with inherent biodegradation test results between 20 and 70%, the Interim U.S. EPA Guidance recommends using a wastewater treatment half-life of 30 hours, which corresponds to a biodegradation rate (k1) of 0.023/hour. The measured sorption coefficient (Kd) of TCC in activated sludge is 17,320 (Table 2.2). The parameters were used in the AS-Treat model to calculate the removal of TCC during wastewater treatment. AS-Treat is a customized version of the SimpleTreat model (Struijs, 1996) allowing for the direct use of Kd and k1. The model predicted the total removal rate of TCC of 63.4%, of which 59.7% was via sorption to sludge and 3.75% due to degradation. This calculated removal rate was lower than the measured removal rates in the CAS study and monitoring studies (see below), probably due to the conservative biodegradation rate used in the model (the CAS study showed that at least 56% of the total removal was due to biodegradation (Table 2.2.) compared to 3.75% predicted by the model).

#### **Monitoring:**

TCC removal values obtained from actual measurements taken from activated sludge systems in the U.S. and Europe are presented in Table 2.4. Based on a combination of the CAS study results (Table 2.2.) and monitoring data, an activated sludge removal estimate of 94% was established for this assessment.

Table 2.4. Removal of TCC in Trickling Filter (TF) and Activated Sludge (AS) wastewater treatment plants based on environmental monitoring data in the U.S. and UK.

TREATMENT	Influent µg/l	Effluent µg/l	Removal (%)	Basis
Trickling Filter	15	5	65	Dayton OH (MSL-1759)
	(n = 6)	(n = 6)	$(n = 3)^*$	
Trickling Filter	27	2	93*	North East/Pensacola FL (MSL-1441)
Trickling Filter	-	7 (n = 3)	-	South East/Lubbock TX (MSL-1442)
TF $(2/3)$ + AS $(1/3)$	50	12	76 <sup>*</sup>	Montclair/Pensacola FL (MSL-1441)
Trickling Filter	0.4	0.076	81	U.K. Stretford Plant (Shuguang Ma 1997)
Trickling Filter	16.3	4.82	70	Glendale OH (Shuguang Ma 1997)
Average TF			77	
Activated Sludge	42	5	88*	Main Street/Pensacola FL (MSL-1441)
Activated Sludge	-	4 (n = 3)	-	#1 & #2/Bakersfield CA (MSL-1442)
Activated Sludge	200	~ 6	98	CAS data (Gledhill, 1975)
Activated Sludge	14.5	0.54	96	Polk Run (Shuguang Ma 1997)
Average AS	-	-	94	

<sup>\*</sup>Calculated removals were based on analysis of grab samples. These removals should be considered only an indication of actual removal rates because large fluctuations in influent concentrations as a function of time are expected.

## [2.3.3] Ecosystem Exposures Related to Manufacturing and Formulation of Triclocarban- Containing Products

#### Manufacture:

There is no TCC manufacture in the U.S.; TCC is imported to the formulation facilities. Hence, this document only discusses the manufacturing processes of the major importers. Total estimated TCC volume imported to the U.S., as identified though information from EPA's non-confidential 1998 IUR, is 250 - 500 metric tonnes/year.

#### Formulation:

TCC is received by the production facilities in 500 kg "supersacks". With the current 3-shift production process, 10 supersacks are used per week, or 260,000 kg per year, approximately one third total U.S. volume. TCC enters the totally closed, dust-free and dedicated production process at the mixer phase. Product at this process stage is a low moisture (~10%) solid being extruded through the product line by rotating screws and air. Only two processes remain after TCC addition, milling and packing. Both processes have dust control measures to contain TCC-containing product (~1%). Waste TCC is kept to a minimum by recycling finish product shavings, dust control systems, and a totally enclosed production process. There is no TCC-containing wastewater disposal from cleaning or production processes. A minimum amount of bulk TCC may be spilled with the opening of each supersack. This material is swept up immediately and disposed to the solid waste stream. This waste material does not enter the aquatic compartment and does not affect the assessment presented in this document.

## [2.3.4] Ecosystem Exposures Related to Consumer Use and Disposal of Products Containing TCC

#### [2.3.4.1] Usage in Consumer Products

The total estimated TCC volume imported to the U.S., from EPA's non-confidential 1998 IUR, is 250 - 500 metric tonnes/year. However, the volume used in the environmental and human health assessments was set at 750 metric tones/year as this represents the upper range of reporting in the 1990 IUR and could represent the upper range of use in the U.S.

#### [2.3.4.2] Consumer Product Releases - Influent Concentration

The concentration of TCC in the effluent from consumer homes is calculated assuming per capita water use is 364 l/cap/day and a U.S. population of 250 million people (defaults from U.S. EPA E-FAST Down-the-Drain scenario). Assuming no loss of TCC in the sewage collection and conveyance system, the influent concentration to the wastewater treatment plant is assumed to be equal to the effluent concentration from the home.

The influent concentration (I) is calculated using the equation:

I = D/(a)(b)(c)

#### where:

D = amount of chemical used per year in consumer products

a = number of days in year

b = water used per capita, and

c = total population

Using this equation the influent concentration of TCC is calculated as:

I = 750,000 kg/yr (10E6mg/kg)/(365 d/y)(364 l/cap/day)(2.5E8 people)

I = 0.02258 mg/L

 $I = 22.6 \,\mu g/L$ 

The average measured influent TCC concentration at a Dayton, OH trickling filter wastewater treatment plant (WWTP) was 15.4  $\mu$ g/L based on samples collected over a three day period (MSL-1759) and influent levels at three treatment plants in Pensacola, FL ranged from 27 to 50  $\mu$ g/L (MSL-1441). These measurements were made in the 1980's. More recently, influent concentrations at two U.S. treatment plants were 14.55 and 16.32 ?g/L for an activated sludge and trickling filter plant, respectively. These measured influent concentrations are comparable to measurements made approximately 15 years ago and demonstrate that TCC use has remained constant in the US. The average of the measured influent concentration was 15.4  $\mu$ g/L, agreeing quite nicely with the predicted values. The slight discrepancy between the predicted value and the actual measured values can be explained in part by: 1) loss of TCC during wastewater conveyance systems (sorption/biodegradation); and/or 2) not all of the manufacturing volume of TCC is disposed down-the-drain.

#### [2.3.4.3] Summary of Predicted and Measured Surface Water Concentrations

#### **Predicted Concentrations:**

The U.S. EPA Exposure E-FAST model was used to calculate the concentrations of TCC in surface waters. The key input parameters in the down-the-drain exposure scenario of the model were the estimated TCC usage rate in the U.S. (750 t/y, section 2.3.4.2) and the wastewater treatment removal rate of 94% (section 2.3.2). The predicted median surface water concentration of TCC was 0.0013 ? g/L, and the high-end concentration was 0.017 ? g/L.

#### **Measured Concentrations:**

Illustrated in Figure 2.1 is the distribution of TCC concentrations measured in U.S. freshwater environments during the 1979 (78 sites) and 1982 (30 sites) samplings (MSL-1264 & ES-84-SS-6). These data indicate that > 90% of the freshwater surface waters in the U.S. contained a TCC concentration of  $< 0.05 \,\mu\text{g/L}$ .

Less intensive sampling efforts were also conducted during 1985 and 1987 at six locations previously sampled during 1979 and 1982. TCC concentrations ranged from  $<0.001~\mu g/L$  to 0.194  $\mu g/L$  for the 1985 sampling (MSL-5342). The range of concentrations observed during the 1987 sampling was  $<0.074~\mu g/L$  to 0.228  $\mu g/L$  (MSL-7813). The use of a less sensitive analytical method for the 1987 sampling limits comparisons to previous data. Data from 1985 and 1987 are summarized in the Table 2.5. Note that the concentrations in the table are given in nanograms/litre and are measured using liquid chromatography (LC) and gas

chromatography/mass spectroscopy (GC/MS). Many of the locations sampled during this period did not have advanced wastewater treatment in place. Improved wastewater treatment systems in these areas would likely improve TCC removal in wastewater and result in decreased levels of TCC in WWTP effluents.

Based on the results from the monitoring studies in 1979, 1982, 1985 and 1987, the TCC concentration of 0.05 ? g/L should be regarded as a high-end predicted concentration in surface waters (PEC). Given that the consumption of TCC has remained constant over the last 15 years (see section 2.3.4.2), this estimate should also adequately reflect the present situation. This estimate is slightly higher than the calculated concentrations of TCC using the E-FAST model and is likely due to the fact that sites more prone to contamination by industrial and household chemicals were selected for environmental monitoring studies.

Robust Summaries of the monitoring studies mentioned in this section are presented in Appendix A of this document.

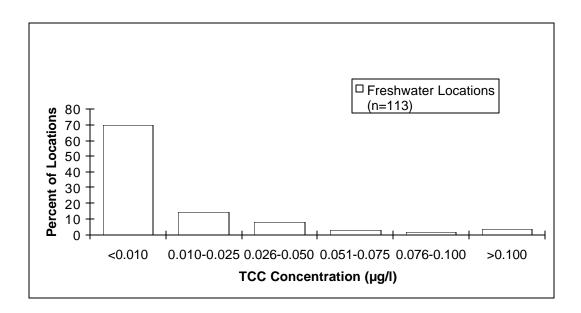

Figure 2.1 Measured Concentrations of TCC in U.S. Surface Waters in 1979 and 1982.

Table 2.5. Measured Concentrations of TCC in U.S. Surface Waters in 1985 and 1987.

SITE	LC (ng/l)	GC/MS (ng/l)

Charles River (Boston Harbour) MA	51 – 89	63 - 77			

#### [2.4] Ecotoxicity

The key ecotoxicity data for TCC are summarized in Table 2.3 above, and the complete list of all available studies are presented in Appendix B. Robust summaries of these studies are presented in Appendix A.

The most sensitive taxa to TCC exposure are aquatic invertebrates. This conclusion is supported by both acute and chronic toxicity information from testing done on a wide range of organisms. The ecotoxicity endpoint employed in the TCC aquatic risk characterization was a 7 day *Ceriodaphnia* study conducted in aged, blended water (Procter & Gamble, ABC # 43812). This endpoint was chosen as it represents an organism from the taxa that is most sensitive to TCC exposure and it is an end point that was developed using standard chronic toxicity test methods. This study resulted in a NOEC of 1.46 µg/L and was completed in 1997 by ABC Labs, Columbia, Mo. TCC exposure concentrations were determined using LC/MS by ABC Analytical. TCC levels that show an adverse effect to fish, the next most sensitive taxa, are at least an order of magnitude greater than those observed for aquatic invertebrates.

Given the abundance of acute and chronic aquatic toxicity data on TCC covering all the key taxonomic categories (algae, invertebrates, fish), an application factor of 10 was deemed appropriate for use in this risk characterization, resulting in the aquatic Predicted No-Effect Concentration (PNEC) of 0.146 ? g/L.

#### [2.5] Environmental Screening Level Assessment

Environmental risk characterization of TCC in the aquatic compartment (ratios of PEC/PNEC) is presented in Table 2.6. Based on both calculated and measured concentrations of TCC, the ratio of PEC/PNEC is below 1. It can be concluded, therefore, that TCC is safe for the aquatic environment at its current rate of consumption.

Table 2.6. Risk Characterization of TCC.

	PEC (? g/L)	PNEC (? g/L)	PEC/PNEC (10 <sup>th</sup> /50 <sup>th</sup> percentile)
Measured	0.050 (high end)	0.146	0.34
Calculated	0.0013 (median)	0.146	0.009
	0.017 (high end)	0.146	0.116

#### [3] Human Health Assessment

#### [3.1] Introduction

Each of the reports obtained was reviewed to determine adequacy according to EPA criteria and reliability per Klimisch *et al.* (1997). Robust summaries were prepared for each report with Klimisch scores assigned according to the guidelines recommended by the EPA (U.S. EPA, 1999) for each study type. Robust study summaries for SIDS endpoints, as well as several relevant beyond SIDS endpoints, with available and reliable (according to Klimisch criteria) data for TCC are provided in Appendix A and are summarized in Tables 3.1. and 3.2.

**Table 3.1. Summary of SIDS Endpoints** 

ENDPOINT	SPECIES	RESULTS	PROTOCOL
Acute Oral Toxicity	Rat	LD <sub>50</sub> >2000 mg/kg bw	Directive 84/449/EEC, B.1
Acute Dermal Toxicity	Rabbit	LD <sub>50</sub> >10000 mg/kg bw	Other (Monsanto Study # Y-63-23)
Repeat Dose Toxicity	Rat	NOAEL = >1000 mg/kg bw	Oral gavage, exposure: 5days/week/30days, 10 rats/sex/group
Genetic Toxicity: Gene mutation	Salmonella typhimurium strains TA 98, 100, 1535, 1537	negative	OECD Guideline 471, With and without metabolic activation
Genetic Toxicity: Chromosome Aberration	Chinese hamster ovary (K-1) cells	negative	EPA OPPTS 870.5375, With and without metabolic activation
Reproductive Toxicity	Rat	NOAEL P = 3000 ppm NOAEL F1 = 1000 ppm NOAEL F2 = 3000 ppm	Three generation reproduction study
Developmental Toxicity	Rat	NOAEL >3000 ppm	Three generation reproduction study

Table 3.2. Summary of Beyond SIDS Endpoints

ENDPOINT	SPECIES	RESULTS	PROTOCOL
Eye Irritation	Rabbit	Slightly-irritating	undiluted, 24 hr. (modified Draize)
Skin Irritation	Rabbit	Non-irritating	25% suspension in corn oil, 24 hr. occluded (Draize)
Sensitization	Human	Not- sensitizing	Shelanski method (Monsanto Study #SH-63-7)
Carcinogenicity	Rat	No evidence of dose- related increase in tumors at any site	EPA OTS 798.3320

#### [3.2] Summary of Hazard Assessment

The following toxicology data are provided in support of the use of TCC in consumer soaps. A summary of each study is presented below. Additional information on these studies, in the form of robust summaries, is provided in Appendix A.

#### SIDS Endpoints

#### [3.2.1] Acute Oral Toxicity in Rats

An acute oral  $LD_{50}$  toxicity study was conducted on TCC. A single dose of 2000 mg/kg bw test material was administered in polyethylene glycol 400 to rats by oral gavage. All animals (5 rats/sex/group) were observed for mortality and clinical signs at 0.5, 1, 2, and 4 hours after dosing and daily thereafter for 14 days.

There were no deaths in any group, therefore the oral  $LD_{50}$  for male and female rats is > 2000 mg/kg bw.

#### [3.2.2] Acute Dermal Toxicity in Rabbits

The acute percutaneous toxicity of TCC was investigated in rabbits. The diluted compound was applied in increasing doses at 0.2 fractional log intervals to the closely clipped, intact skin of New Zealand white male and female rabbits. The treated areas were covered with plastic strips and the animals placed in wooden stocks for periods up to 24 hr, after which time they were

assigned to individual cages. Observations were made for toxic symptoms and, since there were no deaths, no autopsies were performed. The dermal  $LD_{50}$  of TCC is greater than 10,000 mg/kg bw.

#### [3.2.3] Subchronic (30 day) Oral Study

A subchronic feeding study was conducted to assess the potential for systemic toxicity after repeated exposure to TCC. The test substance was administered as a 25% aqueous solution at 500 or 1000 mg/kg bw by gavage, 5 days per week for a thirty day period. Food consumption and weight gain were recorded weekly and observations were made for outward symptoms of toxicity such as reduced activity and non-grooming. At the end of the 30 day period, representative animals from each group were sacrificed.

The feeding of TCC to rats at a daily level of 1000 mg/kg bw, five days per week for thirty days, was not detrimental insofar as could be determined by food consumption, growth data, and tissue examination.

#### [3.2.4] Mutagenicity - Salmonella Reverse Mutation Assay (Ames Test)

The mutagenicity potential of TCC was evaluated using the *Salmonella* Reverse Mutation Assay (OECD Guideline 471) in *Salmonella typhimurium* strains TA98, TA100, TA1535, TA1537. Test material concentrations ranged from 8-5000 ?g/plate in the preliminary toxicity dose range-finding studies and 125-4000?g/plate in the definitive studies. Appropriate positive, solvent and sterility controls were used.

The results of the Ames test indicate that under the condition of these studies, the test material did not show any evidence of mutagenic potential in any of the tester strains in the presence or absence of Arochlor-induced rat S9 liver microsomes.

#### [3.2.5] In Vitro Chromosomal Aberration Study

The objective of this study was to evaluate the clastogenic potential of TCC as manifested by the production of chromosomal abnormalities such as deletions, exchanges, rings and breaks in exposed Chinese hamster ovary (CHO-K1) cells. Mitomycin C and Cyclophosphamid were used as positive controls in the non-activated study and activated study, respectively. Test material concentrations ranged from 33-2000 ?g/ml in the study.

The study results indicate that the compound has no clastogenic potential under the conditions of this test.

#### [3.2.6] Reproductive and Developmental Toxicity

A study was conducted to determine the reproductive and teratogenic potential of TCC in rats in a three generation oral feeding study. TCC was administered for 60 days prior to initiation of mating in the parental generation and 80 days prior to initiation of mating in the F1 and F2 generations at one of the following doses: 250, 500, 1000, or 3000 ppm.

Body weights and food consumption were measured weekly during the study. Observations for mortality and adverse effects were done twice daily. Detailed physical exams were done weekly on all generations. All animals dying spontaneously or killed in a moribund condition were examined and tissues preserved in 10% formalin. Dead or stillborn pups were given a gross postmortem exam and preserved in 70% ethanol. All adult males and females were given a gross postmortem exam and tissues preserved. At weaning (day 21), pups not chosen as future parents were sacrificed and examined with only grossly abnormal tissues preserved. Data were analyzed between control and treated groups.

No treatment-related effect was evident on mortality or physical in-life evaluations. Body weight and food consumption were not adversely affected by treatment throughout the study. Mating indices and male fertility were not adversely affected by treatment for all generations. Pregnancy rates were comparable to controls for dose groups 250 - 1000 ppm. The pregnancy rate was unusually low for the high dose group (3000 ppm) during the second litter interval of the F1 generation only.

The Reproductive No Observed Adverse Effect Level (NOAEL) for Parental and F2 generations = 3000 ppm; NOAEL for the F1 generation = 1000 ppm. No treatment-related effects were seen on any pups from all generations (including dead pups). Litter viability and survival rates were comparable to controls. The NOAEL for teratogencity was greater than 3000 ppm.

#### **Beyond SIDS Endpoints**

#### [3.2.7] Primary Eye Irritation in Rabbits

TCC was evaluated for the potential to cause eye irritation by placing 20.0 mg of finely ground sample in the conjunctival sac of the right eye of each of three albino rabbits. The eyes were rinsed with warm isotonic saline solution after 24 hours. Observations for irritation were made over a period of several days. The data was scored according to the method of Draize.

The maximum average score was 7.3 out of a possible 110. TCC is considered slightly irritating to the eyes of rabbits.

#### [3.2.8] Primary Dermal Irritation in Rabbits

A dermal irritation study was conducted on TCC in rabbits. Finely ground powder as a 25% suspension in corn oil was applied to the clipped intact skin of albino rabbits and removed after

24 hours. The application was covered with plastic strips to retard evaporation and avoid contamination. Observations were made over a period of several days for irritation.

According to Draize scoring, the compound was classified as non-irritating.

#### [3.2.9] Dermal Sensitization

A dermal sensitization study was conducted on TCC in 50 human volunteers. Fifty (50) mg of substance was applied to the gauze portion of patches that were applied to the back of 50 subjects for 24 hours and repeated for 15 applications (with 24 hour rest periods between each repeat application). After a 2 week rest period, a challenge application of 50mg was applied to the same site of each subject for a 24 hour exposure period. Subjects were observed for reactions.

TCC was neither a primary irritant, a fatiguing agent, nor a sensitizer to any of the 50 subjects.

#### [3.2.10] Carcinogenicity test

A 24 month oral feeding study was conducted in male and female Sprague-Dawley rats according to EPA OTS 798.3320 guideline. TCC was administered ad libitum at doses calculated to be 25, 75, and 250 mg/kg body weight.

No evidence of a dose related increase in tumor incidence at any site. No statistically significant difference in tumor incidence between controls and high dose animals (except for a significant reduction in incidence of fibroadenomas and papillary carcinomas in high dose females).

#### [3.3] Worker Exposure Assessment

There is potential for occupational exposure to this material by workers who either produce the raw material or formulate TCC-containing products. The potential routes of exposure that are most relevant during manufacture of TCC and formulation of TCC-containing products are dermal and inhalation exposure.

#### [3.3.1] Manufacturing Facility

For workers, exposure to TCC during the production or transportation process is limited due to the low volatility of TCC and the industrial hygiene standards and personal protective equipment that are utilized as a standard practice in production facilities. Employee exposure is minimized through engineering controls and good industrial hygiene practices.

#### [3.3.2] Formulation Facility

The potential for worker exposure during the manufacture of bar soaps, liquid soaps or body washes containing TCC is minimized through engineering controls, a closed system operation, administrative procedures and personal protective equipment such as safety glasses or goggles, rubber gloves and other protective clothing as appropriate to prevent skin contact. Also, a NIOSH/MSHA (National Institute of Occupational Safety and Health/Mine Safety and Health Administration) approved dust respirator is recommended if the inhalation of dust is possible. A behavior observation and safety sampling system is in place as part of standard operating procedures to reinforce compliance with safe practices.

#### [3.4] Consumer Residential Exposure Assessment

Consumer residential exposure to TCC from product use is expected to be limited based on the use pattern for the product and chemistry of TCC. The potential for consistent consumer exposure to TCC exists through possible lifetime use of personal cleansing products (e.g., bar soaps, liquid soap, and body washes) that may contain TCC. Consumer exposure with the bar soap and body wash forms containing TCC is expected to be the same as or less than with the liquid form. The potential routes of consumer exposure are discussed below and are followed by calculations to estimate the most relevant exposures. Consumer monitoring studies have not been performed, as modeled estimates suffice for this material.

#### [3.4.1] Dermal Exposure

Dermal exposure to TCC is the major route of exposure due to the fact that TCC is utilized in personal cleansing products. Such dermal exposure can occur to the 1) face, 2) hands, and/or 3) body during the cleansing process.

Under typical cleansing conditions TCC containing products are utilized in 'rinse-off' scenarios. It follows that the majority of TCC to which an individual is initially exposed is anticipated to be washed away with the rinse water. In addition, these cleansing exposures are generally of very short duration, which is not considered in the calculations.

The FDA (OTC, 1978) used the following Maibach experiment to estimate absorption at 14% and for calculating safety factors. Maibach demonstrated that when radio-labeled TCC was dissolved in acetone and applied to human skin for 24 hours and not rinsed, up to 14% was excreted by the end of 10 days (Maibach, 1986). However the conditions used (i.e., use of an acetone solution) and the assumption that the absorption was instantaneous, are not directly comparable to TCC exposure as a result of actual product use. In a 'single showering study' conducted by Scharpf *et al.* (1975), TCC was measured directly under product use conditions. These investigators showed that approximately 0.2% of an applied dose of TCC (from 7 grams of a 2% TCC bar soap) was excreted in the first 24 hours. Only 0.39% TCC was absorbed after six days.

A summary of the risk characterization exposure estimates is included in the table below and in more detail in the following section. These exposure estimates are based on a child whose body weight is 10 kg (see children's exposure section for more detail) and a worst case scenario of 5% TCC in product. Additionally, no correction was made for the fact that the habits and practices data gathered by the SDA was based on adult use only. Thus, no correction for a difference in surface area and product usage amounts was included in this exposure estimate calculation, adding another level of conservatism.

Table 3.3. Consumer Dermal-Based Exposure Assessment

ROUTE:	EXPOSURE	RESULTING DOSE
Dermal		
bar soap	0.1 mg /kg bw/day	0.005 mg/kg bw/day
liquid soap	0.11 mg/kg bw/day	0.006 mg/kg bw/day
bodywash	0.07 mg/kg bw/day	0.0004 mg/kg bw/day

[3.4.1.1] Bar Soap

[3.4.1.1.1] Bar Soap – hands

The exposures for hands, face and body are added together for bar soap use to account for a worst case scenario.

Exposure during bar soap use on the hands is given by the following equation (AIHA, 2001):

## (Use /day)( grams used/ use)(% product retained on skin)(% absorbed dermally)(CF) BW

Where: CF: conversion factor (1000 mg/g)

BW: body weight

Assumptions:

- 1. Product is used an average of 6 times/day for hand washing (SDA, 2002)
- 2. The average mass of bar soap utilized per hand wash use = 0.36 g (SDA, 2002)
- 3. The amount of TCC retained on the skin after rinse off use = 1.4% (North-Root et al., 1984).
- 4. The amount of TCC absorbed = 0.39% (Sharpf et al., 1975)
- 5. The conversion factor = 1000 mg/kg
- 6. The 95<sup>th</sup> percentile body weight for a 7 month old male = 10 kg (NHANES, 2002)

#### Exposure =

(6 uses /day)( 0.36 grams / use) (1.4 % product retained on skin)(0.39% absorbed)(1000 mg/g) 10 kg bw

Exposure = 0.012 mg/kg bw/day for hand washing

#### [3.4.1.1.2] Bar Soap - face

Exposure during bar soap use on the face is given by the following equation (AIHA, 2001):

## (Use /day)( grams used/ use)(% product retained on skin)(% absorbed dermally)(CF) BW

Where: CF: conversion factor (1000 mg/g)

BW: body weight

#### Assumptions:

- 1. Product is used an average of 1 times/day for face washing (SDA, 2002)
- 2. The average mass of bar soap utilized per face wash use = 2.7 g (SDA, 2002)
- 3. The amount of TCC retained on the skin after rinse off use = 1.4% (North-Root et al., 1984).
- 4. The amount of TCC absorbed = 0.39% (Sharpf et al., 1975)
- 5. The conversion factor = 1000 mg/kg
- 6. The 95<sup>th</sup> percentile body weight for a 7 month old male = 10 kg (NHANES, 2002)

#### Exposure =

(1 uses /day)( 2.7 grams / use) (1.4 % product retained on skin)(0.39% absorbed)(1000 mg/g)
10kg bw

#### Exposure = 0.015 mg/kg bw/day for face washing

#### [3.4.1.1.3] Bar Soap – body

Exposure during bar soap use is given by the following equation (AIHA, 2001):

## (Use /day)( grams used/ use)(% product retained on skin)(% absorbed dermally)(CF) BW

Where: CF: conversion factor (1000 mg/g)

BW: body weight

#### Assumptions:

- 1. Product is used an average of 1.53 times/day for body washing (SDA, 2002)
- 2. The average mass of bar soap utilized per body wash use = 8.6 g (SDA, 2002)
- 3. The amount of TCC retained on the skin after rinse off use = 1.4% (North-Root et al., 1984).
- 4. The amount of TCC absorbed = 0.39% (Sharpf et al., 1975)
- 5. The conversion factor = 1000 mg/kg
- 6. The 95<sup>th</sup> percentile body weight for a 7 month old male = 10 kg (NHANES, 2002)

#### Exposure =

(1.53 uses /day)(8.6 grams /use)(1.4 % product retained on skin)(0.39% product absorbed)(1000 mg/g)
10kg bw

#### Exposure = 0.072 mg/kg bw/day for body washing

Thus, **total exposure** to TCC under a worst case scenario for bar soap use = (Exposure to TCC from hand washing + face washing + body washing) = <math>(0.012 + 0.015 + 0.072 mg/kg bw/day) = 0.10 mg/kg bw/day

The resulting dose is calculated by:

(exposure) x (the maximum amount of TCC in the product) = (0.10 mg/kg bw/day) x (5%) = 0.005 mg/kg bw/day

The **MOE** is calculated by:

(NOEL for 2 year oral gavage) / resulting dose = (25 mg/kg bw/day) / (0.005 mg/kg bw/day) = **5000** 

#### [3.4.1.2] Liquid Soap

#### [3.4.1.2.1] Liquid Soap -Hands

The exposures for hands and body are added together for liquid soap use to account for a worst case scenario. No face washing is generally anticipated for this product type.

Exposure during liquid soap use is given by the following equation (AIHA, 2001):

## (Use /day)( grams used/ use)(% product retained on skin)(% absorbed dermally)(CF) BW

Where: CF: conversion factor (1000 mg/g)

BW: body weight

#### Assumptions:

- 1. Product is used an average of 8 times/day for hand washing (SDA, 2002)
- 2. The average mass of bar soap utilized per hand wash use = 1.7 g (SDA, 2002)
- 3. The amount of TCC retained on the skin after rinse off use = 1.4% (North-Root et al., 1984).
- 4. The amount of TCC absorbed = 0.39% (Sharpf et al., 1975)
- 5. The conversion factor = 1000 mg/kg
- 6. The 95<sup>th</sup> percentile body weight for a 7 month old male = 10 kg (NHANES, 2002)

#### Exposure =

(8 uses /day)( 1.7 grams / use) (1.4 % product retained on skin)(0.39% absorbed)(1000 mg/g) 10kg bw

Exposure = 0.074 mg/kg bw/day for hand washing

#### [3.4.1.2.2] Liquid Soap - body

Exposure during liquid soap use is given by the following equation (AIHA, 2001):

## (Use /day)( grams used/ use)(% product retained on skin)(% absorbed dermally)(CF) BW

Where: CF: conversion factor (1000 mg/g)

BW: body weight

Assumptions:

- 1. Product is used an average of 0.57 times/day for body washing (SDA, 2002)
- 2. The average mass of bar soap utilized per body wash use = 11.8 g (SDA, 2002)
- 3. The amount of TCC retained on the skin after rinse off use = 1.4% (North-Root et al., 1984).
- 4. The amount of TCC absorbed = 0.39% (Sharpf et al., 1975)
- 5. The conversion factor = 1000 mg/kg
- 6. The 95<sup>th</sup> percentile body weight for a 7 month old male = 10 kg (NHANES, 2002)

#### Exposure =

(0.57 uses /day)(11.8 grams /use) (1.4 % product retained on skin)(0.39% absorbed)(1000 mg/g) 10 kg bw

#### Exposure = 0.037 mg/kg bw/day for body washing

Thus, **total exposure** under a worst-case scenario for liquid soap use =

(Exposure to TCC from hand washing) + (Exposure to TCC from body washing) =

(0.074 mg/kg bw/day) + (0.037 mg/kg bw/day) = **0.11 mg/kg bw/day** 

The resulting dose is calculated by:

(exposure) x (the maximum amount of TCC in the product) = (0.11 mg/kg bw/day) x (5%) = 0.006 mg/kg bw/day

The **MOE** is calculated by:

(NOEL for 2 year oral gavage) / resulting dose = (25 mg/kg bw/day) / 0.006 = **4166** 

#### [3.4.1.3] Body Wash

No separate face and hand washing are expected for this product type.

Exposure during body wash use is given by the following equation (AIHA, 2001):

## (Use /day)( grams used/ use)(% product retained on skin)(% absorbed dermally)(CF) BW

Where: CF: conversion factor (1000 mg/g)

BW: body weight

Assumptions:

- 1. Product is used an average of 1 times/day for body washing (SDA, 2002)
- 2. The average mass of bar soap utilized per body wash use = 12 g (SDA, 2002)
- 3. The amount of TCC retained on the skin after rinse off use = 1.4% (North-Root et al., 1984).
- 4. The amount of TCC absorbed = 0.39% (Sharpf et al., 1975)
- 5. The conversion factor = 1000 mg/kg
- 6. The 95<sup>th</sup> percentile body weight for a 7 month old male = 10 kg (NHANES, 2002)

#### Exposure =

(1 use /day)(12 grams /use) (1.4 % product retained on skin)(0.39% absorbed)(1000 mg/g) 10kg bw

#### Exposure = 0.07 mg/kg bw/day for body washing

Thus, the resulting dose to TCC under a worst case scenario for body wash use = (exposure from body wash) x (maximum amount of TCC in product) (0.07 mg/kg bw/day)(0.5%) = 0.0004 mg/kg bw/day

The **MOE** is calculated by:

(NOEL for 2 year oral gavage) / resulting dose = (25 mg/kg bw/day) / 0.0004 = 62,500

#### [3.4.2] Oral Exposure

There is no anticipated oral exposure under normal use conditions. There is little potential for TCC to be present in drinking water because it is extensively removed during wastewater treatment processes, is biodegradable, and sorptive. Drinking water samples from twelve metropolitan areas in the U.S. had non-detectable concentrations of TCC ( $<0.010~\mu g/L$ ) and confirm this conclusion (Werner and Sehnert, 1980; Monsanto Study Number MSL-1264). Even though the potential for TCC exposure from drinking water is minimal, the E-FAST model was used to conservatively estimate the concentration of TCC in drinking water. The EFAST results were used in the drinking water exposure calculation because the drinking water monitoring

study consisted of a limited number of samples. The results of this model indicate the high end (10% percentile) drinking water results to be  $1.36 \times 10^{-6}$  mg TCC /kg bw/day.

Ingestion of fish is another potential indirect oral exposure pathway for TCC. The log Pow for TCC is 4.2, a value that approaches a level where bioaccumulation in fish is a potential concern. However, actual measured TCC bioconcentration factors (BCFs) in channel catfish ranged from 13 (muscle) to 137 (whole fish) and are much lower than would be expected from a material with a log Pow of 4.2 (Lakinger et al. 1980, Monsanto Report #MSL-1277). The low measured TCC BCFs were the result of rapid metabolism of TCC and excretion of its metabolites. These data suggest that TCC does not bioconcentrate in fish to any significant degree and that measurable oral TCC exposure from ingestion of fish is not likely.

The other potential for oral exposure would only occur following accidental ingestion of the product, which would be a one time or infrequent acute exposure. Based on information collected from a consumer telephone service, Poison Control Centers and national emergency rooms, when accidental swallowing does occur there are usually no symptoms reported. Occasionally, when symptoms do occur they include nausea, vomiting, or diarrhea, which are mild and transient in nature. These symptoms are not specific to TCC since they would arise from accidental exposure to a surfactant-based personal cleansing product containing TCC and are symptoms consistent with ingestion of surfactant-based products.

#### [3.4.3] Inhalation Exposure

Consumer inhalation exposure during product use is limited primarily by the low vapor pressure of TCC. Consequently, there is no potential for inhalation from the liquid forms. In addition there is very little dust involved in transferring a bar of soap from the package to the consumer use, so the potential for inhalation exposure from this action is negligible.

#### [3.5] Human Health Screening Level Assessment

The available data summarized in this document demonstrate that TCC has an acceptable safety profile for use in personal cleansing products. The risk to human health is characterized by comparing the estimated exposure to the NOEL from animal studies. The amount by which the NOEL exceeds the estimated exposure is referred to as the MOE and this should be sufficiently large to account for several sources of uncertainty and variability in extrapolating data from animal studies to humans. The worst-case scenario for dermal exposure to TCC from the use of a personal cleansing product leads to an estimated dose of 0.006 mg/kg bw/day. In comparing this conservative estimate to the results from the oral chronic study where the NOEL is 25 mg/kg bw/day, the high MOE indicates there is no safety concern associated with consumer use of TCC-containing products. For potential oral exposure, if one assumes conservatively that TCC would be present in drinking water and not removed in wastewater treatment facilities, the calculated TCC exposure using E-FAST would be 1.38 x 10<sup>-6</sup> mg/kg bw/day. Comparing the estimated oral exposure to the oral NOEL results in a MOE of many orders of magnitude, even

after accommodating inter- and intra-species variation. Based on the data presented, no adverse effects for humans are expected via any relevant exposure route.

Table 3.4. Consumer Risk Characterization

ROUTE:	EXPOSURE	Resulting Dose*	NOEL	MOE
Dermal				
bar soap	0.1 mg /kg bw/day	0.005 mg/kg bw/day	25 mg/kg bw/day	5000
liquid soap	0.11 mg/kg bw/day	0.006 mg/kg bw/day	25 mg/kg bw/day	4167
bodywash	0.07 mg/kg bw/day	0.0004 mg/kg bw/day	25 mg/kg bw/day	62,500
Oral				
drinking water	Not applicable	1.38x10 <sup>-6</sup> mg/kg bw/day	25 mg/kg bw/day	18,115,942

<sup>\*</sup> The resulting dose takes into account the estimated dermal absorption of TCC of 0.39% based on a published report (Scharpf et al, 1975).

## 3.1.3 STABILITY IN SOIL

#### 3.2.1 MONITORING DATA

Type of measurement : background concentration

Media : surface water

Concentration : Method :

**Result**: Analysis for TCC in surface waters in 78 sites in the United States

demonstrated a geometric mean concentration of 0.020 ppb (range = <0.010 - 0.733 ppb) using a method with a detection limit of <0.010 ppb.

17.09.2002 (8)

**Type of measurement**: background concentration

ld 101-20-2 **Date** 20.12.2002

Media drinking water

Concentration Method

Result Drinking water samples from 12 metropolitan areas had

non-detectable levels of TCC, using a method with a

detection limit of <0.010 ppb.

07.12.1999 (8)

Type of measurement

background concentration Media sediment

Concentration Method

Result Analysis for TCC in lake, river and coastal sediments from

> 72 sites in the United States demonstrated a geometric mean concentration of 44 ppb (range = <20 - 8200 ppb) using a

method with a detection limit of 20 ppb.

07.12.1999 (9)

Type of measurement

background concentration Media other: sewage treatment facilities

Concentration Method

Result The average influent concentration of TCC at 3 secondary

sewage treatment facilities in Florida, USA was 38 ppb

(range = 27-50 ppb).

Average effluent concentrations of TCC ranged from 2-12 ppb,

representing an average 86% reduction in TCC concentration, which is ascribed to sludge adsorption. Measurements of TCC in surface waters at

effluent discharge sites show an immediate dilution of 100x. TCC in the discharge body of water ranged from <0.10 -0.163 ppb in the water column and 64-718 ppb in the sediments. Maximum concentrations were found at effluent

discharge sites.

15.10.2002 (10)

Type of measurement

background concentration Media other: sewage treatment facilities

Concentration

Method

Result The average effluent concentration of TCC at 10 secondary

sewage treatment facilities located throughout the United

States was 5.4 ug/l (range = 2.1 - 12.0 ug/l). The

geometric mean TCC concentration of sludge was 40 mg/kg (range = <1-283 mg/kg). Measurements of TCC concentration in sludge-amended soils dropped dramatically with soil depth: average of 0.42 mg/kg in the first 15cm; 0.07 mg/kg between 15-30cm; and 0.03 mg/kg at 30-45cm. These values

confirm that TCC would be unlikely to migrate into

groundwater.

15.10.2002 (11)

Type of measurement

background concentration

Media

sediment

Concentration

Method

Result Analysis for TCC in lake, river and coastal sediments from

16 sites in the United States demonstrated a geometric mean

ld 101-20-2 **Date** 20.12.2002

concentration of 37 ppb (range = <20 - 1630 ppb) using a method with a detection limit of 20 ppb. 56% of the sites had non-detectable levels of TCC. Two small lakes examined because of high sewage loadings showed very low levels of

TCC in sediments (<20 and 24 ppb).

07.12.1999 (12)

Type of measurement

Media

background concentration

Concentration

Method

other: sewage treatment facilities

Result Average influent and effluent concentrations of TCC were

> monitored at a trickling filter sewage plant in Ohio, USA. Average influent concentration of TCC was 15.0 ppb. Average effluent concentration of TCC was 5.0 ppb. The

average removal of TCC was 35%.

07.12.1999 (13)

Type of measurement

Media

background concentration

surface water

Concentration

Method

Result Surface water samples were collected from over 30 sites,

> mostly in the eastern United States. 70% of the sites had non-detectable levels of TCC. The geometric mean TCC concentration for all water samples was 0.017 ppb. There was no significant increase in TCC concentration when

compared to previous results.

07.12.1999 (14)

Type of measurement

Media

background concentration

sediment

Concentration

Method

Result Sediment samples were collected from over 30 sites, mostly

Concentration

Method

:

ld 101-20-2 **Date** 20.12.2002

Result Sediment samples were collected from 6 sites in the

northeastern United States, where highest environmental

concentrations of TCC had been found. TCC was determined by liquid chromatography (HPLC/UV) and gas chromatography with mass

spectrometry (GC/MS). The range of TCC

concentration from 18 sediment samples was <0.01 - 3.9 ppm.

15.10.2002 (15)

Type of measurement

background concentration

Media

surface water

Concentration

Method

Result Surface water samples were collected from selected East

Coast sites in the United States determined worst case

environmental concentrations of TCC. TCC was determined by liquid chromatography with UV detection (HPLC/UV) and gas chromatography with mass spectrometry (GC/MS). The range

of TCC concentration was <0.032 - 0.24 ppb.

08.12.1999 (16)

Type of measurement

background concentration

Media

sediment

Concentration

Method

Result

Sediment samples were collected from selected East Coast

sites in the United States determined worst case

environmental concentrations of TCC. TCC was determined by liquid chromatography with UV detection (HPLC/UV) and gas chromatography with mass spectrometry (GC/MS). The range of TCC concentration was <0.005 - 0.2 ppm in sediment samples.

08.12.1999 (16)

Type of measurement

background concentration

Media other: sewage treatment facilities

Concentration

Method

Result Average influent and effluent concentrations of TCC were

> monitored at two sewage treatment plants in Ohio, USA, and one sewage treatment plant in Europe. TCC was determined by liquid chromatography with UV detection (HPLC/UV) and liquid chromatography with mass spectrometry (LC/MS/MS). The influent concentration of TCC ranged from 7.01 - 16.32 ppb in the US and 0.30 - 0.43 ppb in Europe. The effluent concentration of TCC ranged from 0.24 - 4.83 ppb in the US and 0.054 - 0.088 ppb in Europe. TCC removal by sewage treatment plants exceeded 96% through activated sludge treatment process and only 70.4% through trickling filter process. The lower TCC levels in Europe were due to the

limited usage of TCC in consumer products.

#### 3.3.1 TRANSPORT BETWEEN ENVIRONMENTAL COMPARTMENTS

Type : desorption Media : water - soil

Air : % (Fugacity Model Level I)

Water : % (Fugacity Model Level I)

Soil : % (Fugacity Model Level I)

Biota : % (Fugacity Model Level II/III)

Soil : % (Fugacity Model Level II/III)

Method : other: soil TLC Method

**Year** : 1979

Method : TLC Method described in Federal Register, Vol.40, No. 123,

1975 and Helling (1968,1971)

Result : immobile - strongly absorbed by soil unlikely to leach into

ground water

**Reliability** : (2) valid with restrictions

Meets generally accepted scientific method and is described in sufficient

detail

Flag : Critical study for SIDS endpoint

14.10.2002 (18)

Type : adsorption Media : water - soil

Air : % (Fugacity Model Level I)
Water : % (Fugacity Model Level I)
Soil : % (Fugacity Model Level I)
Biota : % (Fugacity Model Level II/III)
Soil : % (Fugacity Model Level II/III)

**Method** : other **Year** : 1980

Method : 1)14C-TCC was extracted from (1g) spiked sediment with 10ml

solvent(s) (n=8) at room temperature. 2)Two gram portions of sediment were extracted with 100 ml solvent (n=8) at 85C for 5 hours (Soxhlet method). 3)One gram sediment was digested with 5ml 1N NaOH at 60C for 1 hour, cooled, extracted with 10ml solvent (n=8). In all cases, aliquots measured by 14C-counting and HPLC evaluation. Residues

dried at 80C and evaluated by 14C-counting.

**Result**: Low recovery efficiencies in all methods (up to 75% with

NaOH digestion) strongly suggests an irreversible binding phenomenon of TCC to constituents in the sediment. Level of intact TCC isolated from the sediment suggested approx. 50%

of 14C-TCC had undergone transformation.

**Reliability** : (2) valid with restrictions

Meets generally accepted scientific method and is described in sufficient

Soil : % (Fugacity Model Level II/III)

Method : other Year : 1999

ld 101-20-2 **Date** 20.12.2002

**Method**: The focus of the study was to generate an organic

carbon-normalized sorption coefficient (Koc) that could be used to predict the bioavailable TCC in activated sludge, effluent, river water, and sediments. Samples of the various matrices were analyzed for dissolved organic carbon (DOC) and particulate organic carbon (POC). Total organic carbon (TOC) = (DOC+POC). Mass action and mass balance equations

were used to predict the water soluble or bioavailable fraction of TCC in these samples. Batch equilibrium sorption experiments were done using 14C-labelled TCC. Sorption coefficients were calculated from the ratio of solid phase concentration to aqueous phase concentration.

Result : Matrix TOC Koc log Koc Pred.avail. (mg/l) (l/kg) Fraction

ld 101-20-2 **Date** 20.12.2002

#### 3.6 BOD5, COD OR BOD5/COD RATIO

#### 3.7 BIOACCUMULATION

Species : Ictalurus punctatus (Fish, fresh water)

**Exposure period** : 6 day(s) at 22 °C **Concentration** : .0148 mg/l

BCF : 137 Elimination : yes

Method : other: ASTM

Year : 1980 GLP : no

**Test substance** : other TS: 14C-labelled TCC, purity = 98.2% radio-tagged

Method : Between 13 to 40 small and 13 large channel catfish were continuously

exposed to 14.8 to 35.4 ug/l radio-labelled TCC for 24 hours to 6 days in 100 gallon aquaria. Fish were sacrificed at varying time intervals during uptake and dissected tissues were oven dried. Samples of each tissue were completely oxidized to 14CO2 and counted in a scintillation counter to determine 14C-TCC uptake. Data on 14C content were obtained for each fish separately. Data were converted to ug of TCC, plotted to obtain TCC

concentration and Bioconcentration Factor by Plateau Method.

Data also analyzed by computer program BIOFAC (Blau and Agin, 1978) to obtain uptake rate (k1), the depuration rate (k2), the bioconcentration factor

(BCK = k1/k2) and computer plotted bioconcentration curves.

**Remark** : These BCF's are much lower than one would expect for a chemical such as

TCC. An explanation for the low BCF's is possible because a concurrent metabolism study was conducted. TCC was metabolized to hydroxylated TCC and the sulfate and glucuronide conjugates which are apparently much more rapidly eliminated than TCC. Excretion was primarily biliary via the alimentary canal with significant amounts also excreted in the urine. Very little excretion took place across the gills. This fish metabolism pattern was quite similar to that published for mammalian systems.

**Result**: BCF = 137 (whole fish); 13 (fish muscle)

These data suggest TCC would not bioconcentrate from water to fish to any significant degree and that significant food chain biomagnification is

not likely to occur, especially at the anticipated low exposures.

**Test condition** : Dechlorinated city water: alkalinity = 38-42 ug/l; hardness = 123-142 mg/l;

pH = 7.1-7.7.

Temperature = 22 (+/- 2) degree C.

### 5.4 REPEATED DOSE TOXICITY

Type : Sub-chronic

Species : rat

Sex: male/femaleStrain: Sprague-Dawley

Route of admin. : gavage Exposure period : 30 days

Frequency of treatm. : 5 days per week

Post exposure period

**Doses** : 500 mg/kg bw and 1000 mg/kg bw **Control group** : yes, concurrent no treatment

**NOAEL** : > 1000 mg/kg bw

Method : other: Year : 1960 5. Toxicity Id 101-20-2

Pate 20.12.2002

GLP : no

**Test substance**: as prescribed by 1.1 - 1.4

Method : Each dose and control group contained 10 rats/sex. Animals

were dosed with 25% aqueous solution of TCC at 500 or 1000 mg/kg bw by intubation 5 days per week for a thirty day period. Food consumption and weight gain were recorded weekly and observations were made for outward symptoms of toxicity such as reduced activity and non-grooming. At the end of the 30 day period, representative animals from each group were sacrificed. The viscera of the 1000 mg/kg bw and control groups were examined microscopically and saved for possible future examination. Macroscopic examination was made of mounted tissue from

liver, kidneys, gonads, adrenals, brain, heart, and lungs.

**Result**: The feeding of TCC to rats at a daily level of 1000 mg/kg bw, five days per

week for thirty days, was not detrimental insofar as could be determined by

food consumption, growth data, and tissue examination.

**Reliability** : (2) valid with restrictions

Test substance : other TS: triclocarban, CAS# 101-20-2; purity not noted

Method : Groups of 80 Sprague-Dawley rats/sex were administered TCC

in their diet in doses of 0, 25, 75, and 250 mg/kg bw for 24 months. Interim sacrifices of 10 animals/sex/group were done at 6, 12, and 20 months to follow progression of any compound-induced pathological changes. Clinical evaluation

(hematology, clinical chemistry, and urinalysis) were done on animals at interim sacrifices and at the end of the study. All animals were subject to complete necropsy. All gross lesions were examined microscopically for possible neoplastic changes. The protocol was approved by FDA prior to

its initiation at Bio/Dynamics.

Result : Mortality: no evidence of treatment related mortality

(p=0.53 for males and p=0.52 for females)

Observations: no differences between controls and treated animals in daily physical observations, opthalmic changes.

or food consumption.

Body Weight: slightly lower for high dose males (not

statistically significant); slightly reduced and significant for high dose

females during first 18 months.

Hematology: anemia seen in mid and high dose males and high

dose females.

Blood chemistry: slight increase in alkaline phosphatase, BUN, glucose

and total bilirubin at various time points for high dose males.

Urinalysis: no difference between control and treated

5. Toxicity Id 101-20-2

Date 20.12.2002

animals throughout the study.

Organ weights: significant changes associated with treatment = LIVER for mid and high dosed males and females; SPLEEN for mid and high dose males and high dosed females; TESTES and HEART for high dosed males. No microscopic changes in any organs to account for increase in organ weights, therefore the changes may not be biologically significant. Gross Pathological changes: increase in incidence of small and flaccid testes was observed in high dosed males that died spontaneously or were killed moribund between 12 and 23 months. A similar increase was not apparent at terminal sacrifice.

Neoplastic findings: There was no evidence of a dose related increase in tumor incidence at any site.

**Reliability** : (2) valid with restrictions

Guideline study

07.11.2002 (55)

Type : Sub-chronic

**Species** : rat **Sex** : male

Strain : Sprague-Dawley

Route of admin. : oral feed Exposure period : 8 weeks Frequency of treatm. : daily Post exposure period : no

**Doses** : 25, 75, 250 mg/kg

Control group : no

 NOAEL
 : 75 mg/kg bw

 LOAEL
 : 250 mg/kg bw

Method : other: similar to Combined chronic toxicity/carcinogenicity test

Year

GLP : no data

**Test substance**: other TS: triclocarban, CAS# 101-20-2; purity =98.6%

Method : Three groups of male Sprague-Dawley rats (n=35/group) were

administered TCC in their diets for eight weeks. All animals were observed twice daily for morbidity and mortality. Clinical observations for obvious signs of toxicity were performed once daily. Body weights, food consumption, and detailed clinical observations were recorded weekly. Blood was collected from 5/group every two weeks from the abdominal aorta for evaluation of blood levels of TCC. Animals were discarded without

necropsy.

**Result**: Clinically the animals appeared normal throughout the study.

Mean body weights were lower for the high dose group, as was decreased

food consumption.

No compound-related pathology or histopathology noted.

Reliability : (3) invalid

Meets generally accepted scientific method and is described in sufficient detail; Deficiencies: no control group, no histology of tissues, no blood

chemistry

16.10.2002 (56)

### 5.5 GENETIC TOXICITY 'IN VITRO'

Type : Ames test

System of testing : Salmonella typhimurium strains TA98, TA100, TA1535, TA1537

**Test concentration** : 0, 8, 40, 200, 1000, 5000 ug/plate (test 1); 0, 125, 250, 500, 1000, 2000,

4000 ug/plate (test 2)

Cycotoxic concentr. : up to 2000 ug/plate resulted in no cytotoxic effect, however the test

substance precipitated at 2000 ug and higher

Metabolic activation : with and without

5. Toxicity Id 101-20-2

Date 20.12.2002

Result : negative

Method : OECD Guide-line 471

**Year** : 1991 **GLP** : yes

**Test substance**: as prescribed by 1.1 - 1.4

**Method** : Solvent and negative control:

**DMSO** 

Positive controls:

Sodium azide (10 ug/plate) TA 1535 Nitrofurantoin (0.2 ug/plate) TA 100

4-nitro-1,2-phenylene diamine (10 ug/plate) TA 1537 4-nitro-1,2-phenylene diamine (0.5 ug/plate) TA 98

2-aminoanthracene (3 ug/plate)

Metabolic Activation:

S9 mix prepared from livers of male Sprague-Dawley rats treated with a

single ip injection of Aroclor 1254 at a dose of 500 mg/kg

**Remark**: Due to substance precipitation beginning at 2000 ug/plate, doses of 4000

ug and 5000 ug could not be used for assessment. In spite of the low doses used, the positive controls increased the mutant counts significantly over negative control levels, demonstrating the sensitivity of the test

system.

#### 5.8.1 TOXICITY TO FERTILITY

Type other: three generation study

**Species** rat

Sex male/female Strain : Sprague-Dawley

Route of admin.

Exposure period : F0: dosing began 60 days prior to mating, then continuously thereafter. F1

and F2: dosing for 80-day growth period before mating, then continuously

thereafter.

Frequency of treatm. continuously in diet

Premating exposure period

Male : F0 = 60 days; F1 and F2 = 80 days F0 = 60 days; F1 and F2 = 80 days Female :

**Duration of test** three generations 5. Toxicity Id 101-20-2

Pate 20.12.2002

No. of generation

studies

Doses : 250, 500, 1000, 3000 ppm Control group : yes, concurrent vehicle

NOAEL parental : 3000 ppm NOAEL F1 offspring : 1000 ppm NOAEL F2 offspring : 3000 ppm

**Method** : other: Three generation reproduction study

**Year** : 1979 **GLP** : no

**Test substance** : as prescribed by 1.1 - 1.4

**Method**: Dosing, continually in diet, began at least 60 days prior to mating.

1 male:2 females housed together for 15 days. non-pregnated females housed 1:1 with fertile male.

Each parental generation was mated twice, with a 14 day rest period between weaning of litter and second mating. The first litters were raised to weaning, the second litter was used to continue the study. Body weights and food consumption were measured weekly during the study. Observations for mortality and adverse effects were done twice daily. Detailed physical exams were done weekly on all generations. All animals dying spontaneously or killed in a moribund condition were examined and tissues preserved in 10% formalin. Dead or stillborn pups were given a gross postmortem exam and preserved in 70% ethanol. All adult males and females were given a gross postmortem exam and tissues preserved. At weaning (day 21), pups not chosen as future parents were sacrificed and examined and only grossly abnormal tissues preserved. Data were

analyzed between control and treated groups.

Result : No treatment-related effect was evident on mortality or physical in-life

evaluations. Body weight and food consumption were not adversely affected by treatment throughout the study. Mating indices and male fertility were not adversely affected by treatment for all generations. Pregnancy rates were comparable to controls for dose groups 250 - 1000 ppm. The pregnancy rate was unusually low for the high dose group (3000 ppm) during the second litter interval of the F1 generation. Gestation length, pup viability, litter size at birth, litter survival indices, pup growth, and survival to weaning were comparable to controls for dose groups 250 - 1000 ppm. The mean number of live pups at birth was lower than controls for both litter intervals of only the F1 generation of the high dose group

(3000 ppm).

**Reliability** : (2) valid with restrictions

# 5.8.2 DEVELOPMENTAL TOXICITY/TERATOGENICITY

Species : rat

Sex: male/femaleStrain: Sprague-Dawley

Route of admin. : oral feed

**Exposure period**: F0: dosing began 60 days prior to mating, then continuously thereafter. F1

and F2: dosing for 80-day growth period before mating, then continuously

thereafter.

Frequency of treatm. : continuously in diet
Duration of test : three generations

Doses : 250, 500, 1000, 3000ppm Control group : yes, concurrent vehicle

NOAEL maternal tox. : > 3000 ppm

5. Toxicity Id 101-20-2

Date 20.12.2002

NOAEL teratogen. : > 3000 - ppm

**Result**: No treatment-related effects were seen on any pups from all generations.

**Method** : other: Three generation study

Year :

GLP : no

**Test substance**: as prescribed by 1.1 - 1.4

**Method**: Dosing, continually in diet, began at least 60 days prior to mating.

1 male:2 females housed together for 15 days non-pregnated females housed 1:1 with fertile male.

Each parental generation was mated twice, with a 14 day rest period between weaning of litter and second mating. The first litters were raised to weaning, the second litter was used to continue the study. Body weights

weahing, the second litter was used to continue the study. Body weights and food consumption were measured weekly during the study. Observations for mortality and adverse effects were done twice daily. Detailed physical exams were done weekly on all generations. All animals dying spontaneously or killed in a moribund condition were examined and tissues preserved in 10% formalin. Dead or stillborn pups were given a gross postmortem exam and preserved in 70% ethanol. All adult males and females were given a gross postmortem exam and tissues preserved. At weaning (day 21), pups not chosen as future parents were sacrificed and examined and only grossly abnormal tissues preserved. Data were

analyzed between control and treated groups.

**Result** : No treatment-related effects were seen on any pups from all

generations (including dead pups). Litter viability and survival rates were comparable to controls. One dead female F1b pup had clubbed legs and a filamentous tail (250 ppm group); one dead female F1b pup had a spina bifida malformation (1000 ppm group); in the F2b litter, one dead pup was

edematous (250 ppm) and one had a kinked tail (250 ppm); no

malformations seen in the F3 litters.
